13 INTRODUCTION

14 Currently, metastatic breast cancer is difficult to treat. Patients with Hormone Receptor-positive (HR+) and Human Epidermal Growth Factor Receptor 2-negative (HER2-) breast cancer, the most common
15 subtype, typically undergo endocrine therapy. Therefore, new treatments can be very useful in improving
16 quality of life, reducing toxicity, and decreasing scenarios of hormonal resistance. Medications from
17 the group of cyclin-dependent kinase inhibitors appear as a potential improvement in the therapeutic
18 approach to advanced breast cancer. Within this group, there are palbociclib, ribociclib and abemaciclib.
19 Cyclin-dependent kinases 4 and 6 (CDK4/6) are responsible for regulating the cell cycle at the transition
20 between the G1 and S phases. In many neoplasms, this cycle is deregulated, and it promotes uncontrolled
21 cell proliferation. It is then possible for these medications to have better effectiveness. These medications
22 were approved by INFARMED, I.P. after an analysis of the therapeutic value they offer. This decision
23 was made based on data provided by clinical trials done with these medications. The MONALEESA
24 [8, 10, 12] studies were used for ribociclib, PALOMA [13, 9, 4] for palbociclib, and MONARCH [5, 11] for
25 abemaciclib. These studies focused on testing the hypothesis of treating CDK4/6 inhibitors in combination
26 with an aromatase inhibitor or fulvestrant as an alternative to the gold standard. In these research findings,
27 it was determined that there was a notable enhancement in effectiveness, supporting their application
28 in clinical practice. However, this evaluation was based on clinical trials with very specific inclusion
29 and exclusion criteria and in a highly controlled environment. It is then vital to study how these new
30 molecules compare to current practice in terms of treatment effectiveness in a real-world setting. In the
31 meticulously controlled setting of clinical trials, patient selection often skews towards relatively healthier
32 individuals with fewer comorbidities. However, in real-world clinical practice, patients present a diverse
33 range of health profiles, co-existing illnesses, and medication histories that may influence drug efficacy
34 and safety. Real-world data, drawn from electronic health records, insurance claims databases, and patient
35 registries, offers the advantage of reflecting a more heterogeneous patient population, thus potentially
36 uncovering insights not readily apparent in clinical trial settings. Understanding the effectiveness and
37 safety of CDK4/6 inhibitors in real-world conditions is crucial for tailoring more individualized treatment
38 regimens, optimizing outcomes, and enhancing the quality of life for patients with HR+, HER2- breast
39 cancer [7]. Nevertheless, observational studies have inherent limitations, such as confounding by indication,
40 which can lead to biased estimates of treatment effects. To tackle this, there are causality-based assessments
41 that can be employed in order to better estimate the causal effects of treatments. Incorporating statistical
42 techniques like Inverse Probability of Treatment Weighting (IPTW) can play an essential role in enhancing
43 the quality of real-world evidence by accounting for treatment selection bias and balancing observed
44

covariates between treatment groups. IPTW, grounded in the framework of causal inference, allows for the mimicking of a randomized control trial-like setting within observational studies. By assigning weights to individual patients based on their propensity scores—the likelihood of receiving a particular treatment given a set of observed characteristics—analyses can achieve a balance between different treatment arms, thereby reducing bias and confounding factors. Establishing causality, rather than mere association, is vital for the robust interpretation of real-world data. As we strive to understand the long-term impact, efficacy, and safety of CDK4/6 inhibitors in HR+, HER2- breast cancer, the rigorous application of IPTW and causal inference methods can substantially augment the validity of real-world findings, making them a more reliable basis for clinical decision-making [1, 2] So in this paper, we propose:

- To compare the effectiveness of the CDK4/6 inhibitors drug class in terms of progression-free survival (PFS) and overall survival (OS);
- Assess the Hazard Ratio of using the CDK4/6 inhibitors drug class in terms of PFS and OS.
- To compare the effectiveness of CDK4/6 inhibitors in combination with an aromatase inhibitor or fulvestrant with the current standard of care in terms of PFS and OS in patients with HR+, HER2- advanced breast cancer.
- assess the differences in effectiveness between the three CDK4/6 inhibitors in combination with an aromatase inhibitor or fulvestrant in terms of PFS and OS with causality principles in mind, especially the counterfactual theory and IPTW ;

MATERIALS AND METHODS

0.1 Study Design

This retrospective study was designed in 2022. The aim of the study was to evaluate the clinical benefit and long-term survival of patients with HR+/HER2- that started treatment with CDK4/6 inhibitors plus endocrine therapy in different lines of treatment between the 14th of March 2017 and the 31st of December 2021. The follow-up period was set until June 2022. Inclusion criteria: postmenopausal women, men, Oestrogen Receptor positive % (defined by ER expression ≥ 1 % of tumour cell by immunohistochemistry, IHC) and HER2 negative (by IHC and/or amplification assay) in the primary tumour or metastatic site after biopsy. Exclusion criteria: Patients that had only ambulatory medication, and patients involved in clinical trials, diagnosed with other neoplasms or with active treatment during the study period. The comparison group was defined by a population of patients, that were treated with hormone therapy as first-line (due to bone metastases) between 2015 and 13 of March 2017.

The evaluation of effectiveness will involve overall survival and progression-free analysis. We will compare the three different cyclin-dependent kinase inhibitors in terms of efficacy in real-world patients and will also compare the effectiveness of this class of drug against traditional endocrine therapy.

0.2 Data collection

All data were collected from original medical records from baseline to last visit or death. The data was collected from Instituto Português de Oncologia – Porto (IPO-P). Table 1 shows a comparison between the groups. Data included for population treated with CDK4/6 inhibitors plus endocrine therapy : demographic information, age at first diagnosis and age at the beginning of treatment, clinical characteristics and performance status by Eastern Cooperative Oncology Group scale (ECOG), treatment line and treatment schema - CDK4/6 inhibitor and endocrine therapy, stage of the cancer, site of metastases (bone, soft tissue, visceral, visceral and bone, central nervous system-CNS with or without another site). Data included for population treated with endocrine therapy as first-line: demographic information, age at first diagnosis and age at the beginning of treatment, clinical characteristics and performance status by Eastern Cooperative Oncology Group scale (ECOG), stage of the cancer.

For comparison purposes, we used palbociclib and ribociclib since we had a small number of patients treated with abemaciclib (12).

0.3 Statistical Analysis

R was used for statistical analysis. Demographic, clinical characteristics and side effects were analyzed using descriptive statistics (count, percentages and median/range). Kaplan–Meier test was used to determine the median PFS and OS in the entire population and subgroups. Log-rank test was used for comparisons of PFS and OS among different subgroups. Cox Regression was used to assess feature importance and impact. All statistical tests were two-sided, and the significance level was 0.05. The evaluation of the proportional hazards assumptions was done by Schoenfeld residues analysis. We applied propensity score

weights to achieve a more robust comparison between the two groups of CDK4/6i. We used the existence of visceral metastases, treatment line, age at treatment start, and stage. We used the WeightIt package for R [6]. We applied the weights to the Kaplan-Meier curves and to the Cox Regression. We applied the weights to get the ATE which is $E[Y_i(1) - Y_i(0)]$, the average effect of moving an entire population from untreated to treated, or from one drug to the other. Weights were used instead of matching since it is more suited for calculating ATE and the need to preserve the sample size since it is already small from the start. The formula for calculating the weights was through propensity score weighting with GLM. Multiple comparisons were done with the Benjamini-Hochberg (BH) method.

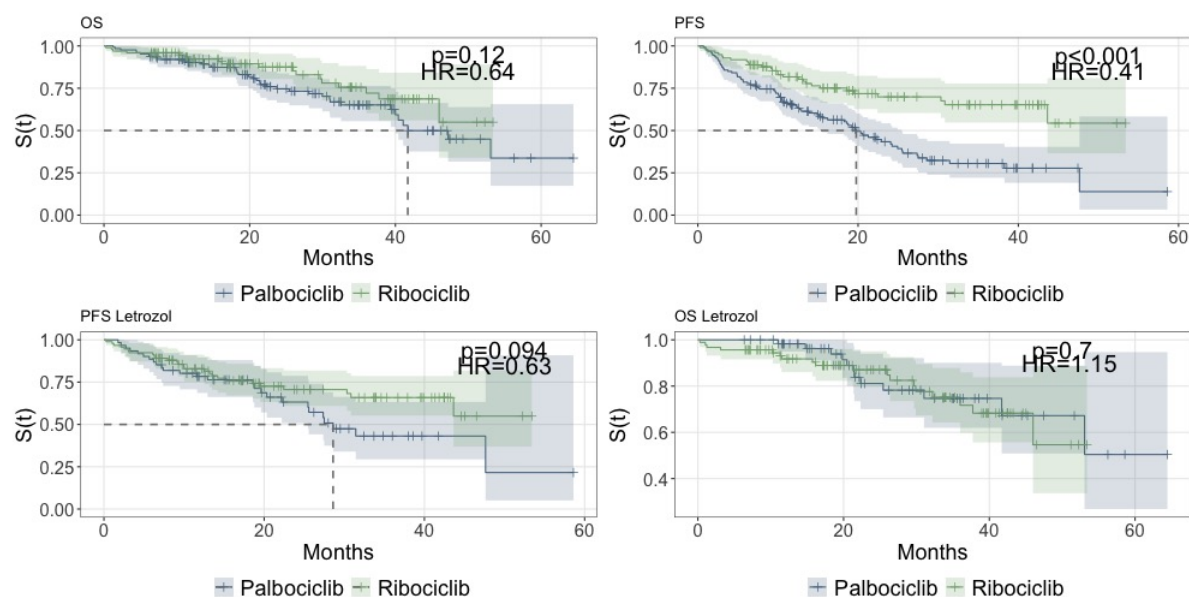

RESULTS

The median OS in the entire population treated with CDK4/6 inhibitors was 46 months (95%CI 39.4–55.6). Median PFS was 20.1 months (95%CI 18.3–24.2). Following this, we compared Palbociclib and ribociclib as first-line treatments. We found that regarding OS, there is no significant difference between the two, but ribociclib is significantly better in terms of PFS (p-value ≤ 0.001) (figure 1). Additionally, we compared the same CDK4/6 inhibitors with letrozol as a combination only. Regarding this scenario, we found out that both were similar in terms of OS and PFS.

We then compared both with a cox regression, where OS shows no significant difference between palbociclib and ribociclib but a significantly better PFS for ribociclib (figure 2) HR 0.60 [95%CI 0.36-0.97] when adjusted to the stage, visceral metastases, age, treatment line, combination and ECOG. This data implies that ribociclib reduces the risk of the disease progression by 40% compared to palbociclib when adjusted for the variables mentioned. The proportional hazards assumption was confirmed with p values all over 0.10.

When comparing endocrine therapy with CDK4/6 inhibitors as first-line treatment (figure 2), we see that only Ribociclib is significantly better in terms of PFS and OS (p-value ≤ 0.001). When comparing palbociclib as the first line, we see that there is no significant difference in terms of PFS and OS (p=0.6 and 0.47). We also applied the same analysis as above, comparing only the letrozol combination with letrozol alone. We found that both ribociclib and palbociclib are significantly better in terms of PFS (HR 0.51 for palbociclib and 0.28 for ribociclib).

Figure 1. Survival curves for Palbociclib and Ribociclib (1st line) - Progression Free Survival and Overall Survival

When comparing palbociclib and ribociclib adjusted for ATE weights, we found a different scenario from previous assessments. There is a significant difference between the two in terms of OS and PFS (figure 3). We calculated the weights taking into account stage, age at treatment start, treatment line, and ECOG.

The Cox regression adjusted for weights shows that ribociclib is not significantly different from palbociclib for OS. The HR for PFS is 0.54 [0.31-0.94; $p=0.029$], implying that ribociclib reduces the risk of the disease progression by ~50% compared to palbociclib when adjusted to the stage, combination drug, treatment line, visceral metastasis, age, and ECOG. Proportional hazard assumptions are confirmed as well.

DISCUSSION

The aim of this study was to evaluate the real-world use of palbociclib and ribociclib in combination with ET for HR+/HER2– and compare this drug class with traditional endocrine therapy. Few real-world evidence studies of palbociclib and ribociclib used in daily clinical practice have been published identifying clinical benefit, patient profile, and sequencing of treatment, with even less evidence for the Portuguese population.

When comparing with clinical trials, regarding patient profile, in our study, 51% had visceral metastasis and 35% had bone-only metastases compared with 49% and 38% in PALOMA-2, and 60% and 25% in PALOMA-3, respectively [9, 3]. As for ribociclib and bone-only metastases, MONALEESA-7 [12] has 24% and MONALEESA-2 has 40% [8] and our study has 30%.

Of note, the range of median PFS for first-line palbociclib was 15.5–25.5 months, which is shorter than 27.6 months observed in a post hoc analysis of the PALOMA-2 clinical trial with extended follow-up [9], but in line with RWE studies (13.3–20.2 months) [7]. When assessed with only letrozol as a combination, the median PFS increased to 28.6 months [95% CI 25.5–not reached]. As for ribociclib, median survival time was not reached whether in OS and PFS. So we can at least say that the median PFS is longer than 50 months. This is longer than the median progression-free survival of 23.8 months (95% CI 19.2–not reached) reported in the MONALEESA-7 trial [12] and longer than 25.3 months (95% CI 23.0–30.3) in the MONALEESA-2 trial [8].

Regarding the comparison between ET and CDK4/6i first line, we found out that neither OS and PFS have significant changes when compared ET to Palbociclib 1st line. We can see the values similar to clinical trials when comparing only the letrozol group (both combination and letrozol alone). For this subgroup, we have similar results to clinical trials, with palbociclib being significantly better, with an HR of around 0.5.

Ribociclib is significantly better for the PFS when compared with letrozol and fulvestrant and with letrozol alone, with an HR of around 0.29 for PFS and 0.28 for ribociclib. This would imply that a combination with fulvestrant should be more effective when used with ribociclib and palbociclib. To note,

Table 2. Cox Regression with palbociclib and Ribociclib - Progression Free Survival and Overall Survival

Characteristic	OS			PFS		
	HR [†]	95% CI [†]	p-value	HR [†]	95% CI [†]	p-value

3	12.4	3.55, 43.1	<0.001	0.39	0.05, 2.87	0.4
[†] HR = Hazard Ratio, CI = Confidence Interval						

that despite their results, the values in table 2 suggest that when we adjust for the variables indicated, ribociclib is significantly better than palbociclib in terms of PFS with an HR of around 0.6.

When comparing with propensity scores weighting, we found out that ribociclib is significantly better than palbociclib for PFS. Our findings suggest that ribociclib could be a better approach for treating HR+, HE- metastatic breast cancer, providing a median OS of over 40 months and median PFS of around 42 months.

CONCLUSIONS

For conclusions and next steps, we feel we have demonstrated that the ribociclib is a good alternative to palbociclib. We still do not have sufficient evidence to state that palbociclib is actually better than endocrine therapy regarding Overall Survival. However, it is sufficient to state that CDK4/6i have an impact on PFS. Further information about the population could be interesting, as well as providing information about safety, economic impact, and quality of life. The characterization of the population in terms of biomarkers could be very useful. We aim to address those issues in sequencing papers. Finally, since all of this data was collected from a single institution, we can not generalize the results to the entire population. However, we believe that this study can be used as a starting point for further research in this area. Additionally, this evidence was generated from observational data. Although we adjusted for confounding factors, we cannot exclude the possibility of residual confounding. However, the propensity scores matching allows for a more robust comparison between the two groups, there is still the possibility of unmeasured confounders.
